ABSTRACT
A comparative study concerning the inhibition of the enzymatic browning in apple juices stored for 24 hours at room temperature (25°C) was carried out between the natural extract of some vegetables and Oyster mushroom with different extraction methods (water, ultrafiltration and alcoholic). The colour changes were assayed quantitatively involved % inhibition using Hunter Lab colorimeter and polyphenoloxidase activities. The results showed that higher inhibition of enzymatic browning was obtained at the end of 24 hour storage period with the extracts of squash, cucumber and pepper followed by mushroom in apple juices. Meanwhile alcoholic and UF extracts were effective in maintaining the storage quality of apple juices. They were found as effective inhibitors. The obtained results confirmed the presence of a proportional relation between the natural vegetable extracts by different extraction methods and their inhibitory effect, whereas the Oyster mushroom extracts in storage time (24 hours) showed an opposite trend. The inhibitory effect of the natural squash extract was comparable with its different extraction method and being higher than pepper and cucumber under all experimental conditions. The natural extracts derived from vegetables were more active than their counterpart derived from mushroom. However, each of them could be considered as potential natural inhibitor having technological and commercial benefits to be applied in processed fruits.

Key words: Enzymatic browning, polyphenoloxidase, colour, apple, juices, cucumber, pepper, squash, Oyster mushroom, extracts, water, alcoholic, ultra-filtration.

INTRODUCTION
Browning occurs usually in certain fruits and vegetables during post harvest, handling, processing operations and storage after harvest. The browning phenomenon is mainly due to the enzymatic oxidation of endogenous phenolic compounds catalysed by polyphenol oxidase (PPO, EC 1.14.18.1) or tyrosinase inherent in biological tissues (McEvily et al., 1992). The PPO is a copper-containing enzyme that catalyses, in the presence of oxygen, the oxidation of diphenols to o-quinones which further lead to polymerizing brown pigments. It is impossible to neglect this PPO-catalysed browning in color occurring in food and food stuffs because unpleasant appearance and concomitant generally result in loss of nutritional and market values (Lee 1992). However, apple is one of the most popular fruits, consumed all over the world and thus the susceptibility of apple and their products to enzymatic browning (PPO). The enzymatic browning of apple has been investigated by many researchers (Murata et al., 1995 and Mi et al., 2002), since enzymatic browning of this particular fruit is an important topic from the standpoint of food science and technology (Iyidogan and Bayindirh 2004 and Eissa et al., 2006).

The PPO-catalysed browning of food can be prevented by the addition of bisulfite (Regina and Goreti 2001), reduced glutathione and thiol-compounds (Sezgintürk, and Dinçkaya 2004; Regina and Goreti 2001 and Eissa et al., 2006) as well as L-cysteine (Hülya and Ayten 2002; Emine and Sule 2004; Eissa et al., 2006). Thereby several studies have been devoted to the non-sulfite anti-browning agents, among these browning inhibitors, ascorbic acid and its derivatives and 4-hexyl resorcinol (4HR) have been used commercially with limited success (Cowan et al., 2000; Hülya and Ayten 2002; Emine and Sule 2004).

For instance, sulfites are commercially used as effective inhibitors for PPO but these compounds have been restricted by the Food and Drug Administration (FDA) due to the possibility of its associated potential hazards. Although the bisulfites are effective to prevent browning, they could be harmful for human health, especially in asthmatic patients. However, these compounds can have adverse health effects and can also react with other components in the food system, resulting in unwanted effects (Sapers et al., 1989 and McEvily et al., 1992). The need for a safe and effective PPO inhibitor has...
focused the research in the finding of natural inhibitors for PPO.

From this concept, there have been a lot of reports on the PPO inhibitors occurring in natural extracts or resources like honey (Oszmiansky & Lee, 1990), some fruits such as Pineapple and lemon juices (Patricia et al., 1993), Some of the leafy vegetables extracts, such as cabbage,mallow, fenugreek leaves, fig leaves and celery, contain ascorbic acid and sulfur dioxide (SO$_2$) (Eissa and Salama 2002 and Ohad et al., 2006), some of spices extracts such as cardamom, clove and ginger are considered to be anti-browning agents of apple products (Eissa et al., 2003 a, b) as well as numerous species of mushrooms, including Agaricus bisporus (Esp’ n et al., 1999 and Sibel et al., 2004) and ‘Enokitake’ mushroom (Mi et al., 2002).

The use of natural extracts by different methods, a powerful anti-browning agent, is discussed more because of the potential hazards of chemical agents. Thus, an active field of research is currently under development to find non-sulfite anti-browning agents as natural extracts by different methods for food industry (Cowan 1999; Son et al., 2001; Mi et al., 2002; Eissa and Salama 2002; Iyidogan and Bayindirh 2004; Sibel et al., 2004; Eissa et al., 2006 and Ohad et al., 2006).

However, no reports have been found on the inhibitory effect of edible ‘Oyster’ mushroom and some vegetables (cucumber, squash and pepper) on PPO activity so far. Because of, there is an increasing demand of consumers for substituting synthetic compounds with natural substances as food ingredients. Therefore, the compounds inherent in natural origins are widely accepted by consumers in the market. This study was designed for the search of natural browning control agents, because PPO inhibitors isolated from regularly consumed foods may be safer compared to non-natural products.

Due to the properties of red delicious apple juices but higher rates of browning, it will be beneficial to investigate the effectiveness of different natural extracts (squash, cucumber, pepper and mushroom) with different extraction methods on enzymatic browning in the red delicious apple juice. The main objective of this work was to study the inter-related effects of squash, cucumber, pepper and Oyster mushroom extracts on enzymatic browning (PPO) in apple juices. Also, to evaluate the inhibitory pattern of the natural vegetables and ‘Oyster’ mushroom extracts that well documented to have anti-browning effects in vivo against the enzymatic browning of apple juices stored for 24 h at 25°C in comparison with the different extraction methods.

**MATERIALS AND METHODS**

**MATERIALS**

**APPLE FRUITS**

Apples: Red delicious (*Malus domestica c.v Borkh*) were purchased from local market at the commercial maturity stored at 4°C until used in about 2-3 days. The Delicious cultivar was chosen because of its wide popularity as a food and rapid browning of the juices after preparation. Apple fruits were washed with water before the treatment.

**PREPARATION OF MUSHROOM**

Fresh cultivated Oyster Mushroom (P. Sajor-Caju, strain 290) on rice straw was purchased from the Center of Mushroom service (Comet, Com. Cairo, Egypt). Oyster Mushroom was washed with cold water and blanched with steam for 7 min, dried by air drier oven heated to 60°C for 4.5 h. and milled. The use of heat during drying hardens the texture and completely inactivates the enzyme polyphenoloxidase (PPO) in mushrooms (Paeaekkoenen and Kurbela (1987).

**PREPARATION OF SOME VEGETABLES**

Cucumber (*Cucumis sativus L*.), squash (*Cucurbita pepo L.*, cv. summer, mainly zucchini) and green pepper (*Capsicum annum L.*, cv. Golden Summer) were purchased from the store of the Ministry of Agriculture, Cairo, Egypt, at the commercial maturity and stored at 4°C until used in about 2-3 days. All vegetables (cucumber, squash and green pepper) were prepared by washed with water, sliced, trimmed, the cores discarded and the seeds and interlobular material removed.

**PREPARATION OF APPLE JUICE**

Apple (Red delicious) samples representing common cultivars were obtained from local food stores and stored briefly at 4°C until needed. One hour prior to use, fruits were removed from the refrigerator and equilibrated to room temperature. Apple fruits were rinsed with water, sectioned to longitudinal slices. Apple juice samples were prepared from individual apples (*red delicious*) with a juicerator and filtered by 3 layers of cheese cloth. Juice was collected in a beaker containing 5mg ascorbic acid / 100ml juice with stirring. The amount of ascorbic acid used was not enough to prevent browning for more than 1 hr. However, the ascorbic acid was used to prevent instantaneous browning, thereby providing a short lag time to allow test materials (natural extracts) to be added and mixed (Sapers and Douglas, 1987).

**PREPARATION METHODS OF NATURAL EXTRACTS**

**WATER EXTRACTION**

Samples of mushroom and vegetables were mixed by blender with hot water (55-60°C) at the concentration of 20% (w/v) for 30s. The aqueous extract was allowed to cool to 25°C and filtered by three layers of cheese cloth, as described by the method of Aselahrou, et al (1997). The solution was centrifuged (3000 rpm for 10 min) and the supernatant was retained. Under the above conditions, the extent of extraction of mushroom and vegetables reached up to 90%. The filtered material was used as a source of PPO inhibitors.

**ULTRA-FILTRATION EXTRACTION**

Ultra Filtration extraction of mushroom and

The article can be downloaded from http://www.ijfans.com/currentissue.html
vegetables was carried out according to the method of Gandia-Herrero et al., (2003) with some modifications.

120 g of some vegetables and mushroom were homogenized in model MORAT-Motor-Stirrer R 270 (Franz MORAT KG, GmbH & Co., Frano ® - Geratechnik, Germany) with 240 ml of 50 mM sodium phosphate buffer (pH 7), at 4 °C. The homogenate was filtered through two layers of cheese cloths and centrifuged at 5000 rpm for 40 min. The sediment was discarded and the supernatant was ultra filtered or passed through 62 mm diameter DIAFLO Ultra-filtration membrane (DIAFLO-UF membranes, AMICON, INC., Beverly, MA, USA) having molecular weight cut-off (MWCO) value of 10,000 Dalton under pressure of 60 Psi at 4 °C and N2 40 kg.cm-2 (76 mm in diameter, Millipore corporation, Bedford, MA 01730, USA). The filtered material was used as a source of PPO inhibitors.

ALCOHOLIC EXTRACTION

Alcoholic extraction of mushroom and some vegetables was carried out according to the method of Cowan (1999) with some modifications.

40 g of vegetables fruits and mushroom were homogenized in model MORAT-Motor-Stirrer R 270 (Franz MORAT KG, GmbH & Co., Frano ® - Geratechnik, Germany) with 100 ml of methanol (methanol) for 30 min. The homogenate was filtered through two layers of cheese cloths and centrifuged at 3000 rpm for 20 min. The sediment was discarded and the supernatant was mixed with the same volume of distilled water. The methanol in the mixture was evaporated using Rotavapor (Model: RE121-type: B -461, Büchi, Lab. AG, CH 9230, FLAWIL / SCHWEIS) at 300 rpm and 50 °C with oil pump under vacuum (TEISTAR, CE, Spain) to evaporate all methanol from samples mixture extract. The extract after evaporation of methanol was used as a source of PPO inhibitors.

APPLE JUICE TREATMENTS AND PROCESSING

Apple fruit were washed under water current and juiced with ordinary domestic food processor. Samples of juice (100 ml) were poured into beakers containing 1% concentration of the natural extracts (vegetables or mushroom) by water, UF and alcoholic extraction and immediately stirred with a magnetic stirrer for 24 hours. A juice sample containing no natural extracts was considered as control. Each prepared sample was immediately subjected to absorbance and colour measurements as well as estimation of polyphenoloxidase enzyme activity during storage at 4°C for 24 hours.

EVALUATION OF BROWNING CAPACITY IN APPLE JUICE

Portions of Cucumber, Squash, Green Pepper and Mushroom natural extracts treated juice and untreated sample (25ml in 50ml beakers containing magnetic stirrer bars, covered to prevent evaporation), were stirred at 400 rpm for as long as 24 hours at room temperature on a stirrer to accelerate enzymatic browning if it were to occur. Juices were held at room temperature with stirring during which time tristimulus reflectance L*, a* and b*-values for controls and treated juices were periodically measured during 24 hours, using a spectro colorimeter (Hunter, LabScan XE, USA) with White Tile of Hunter Lab Color Standard (LX No.16379): X = 72.26, Y = 81.94 and Z = 88.14 (L*= 92.46; a*= -0.86; b*= -0.16) (Sapers and Douglas, 1987). Also, the tristimulus reflectance L*, a*- and b*-values for controls and treated juices were periodically measured at 1, 30, 60, 120, 180 and 360min., and after 24 hours during storage at 4°C for 24 hours.

ANALYTICAL METHODS

POLYPHENOLOXIDASE ACTIVITY

Polyphenoloxidase (PPO) enzyme activity was determined using 0.1M catechol as substrate in sodium phosphate buffer (pH 7.0) according to the procedure given in the study of Özoğlu and Bayindirh (2002). One unit of enzyme activity for polyphenoloxidase was defined as 0.001 Δ A 420 S-1 under the assay conditions.

ABSORBANCE MEASUREMENT (A420nm)

Absorbance values at λ 420nm were recorded with 4054 U.V / visible spectrophotometer (LKB-Bioschrom) according to the method of Iyidoğan and Bayindirh, (2004).

COLOR MEASUREMENTS

Objective evaluations of apple juice samples were measured. Hunter a*, b* and L* parameters were measured with a color difference meter using a spectrocolorimeter (Tristimulus Color Machine) with the CIE lab color scale (Hunter, Lab Scan XE - Reston VA, USA) in the reflection mode. The instrument was standardized each time with white tile of Hunter Lab Color Standard (LX No.16379): X= 72.26, Y= 81.94 and Z= 88.14 (L*= 92.46; a*= -0.86; b*= -0.16) (Sapers and Douglas, 1987). The Hue (H)*, Chroma (C)* and Browning Index (BI) was calculated according to the method of Palou et al., (1999) as follows:

\[ H* = \tan^{-1} [b*/a*] \]
\[ C* = \sqrt{a^*^2 + b^*^2} \]
\[ BI = [100 (x-0.31)] 10.72 \]

Where:

\[ X = (a^* + 1.75L^*) / (5.645L^* + a^* - 3.012b^*) \]

ESTIMATION OF INHIBITION

The browning inhibition based on L-mesurments and A 420 was calculated by using the equations of Iyidoğan and Bayindirh (2004):

\[ \text{Inhibition}(% ) = \left( \Delta A_{420}^\text{control} - \Delta A_{420}^\text{treatment} \right) \times 100 / \Delta A_{420}^\text{control} \]

\[ \text{Inhibition}(% ) = (\Delta L^\text{control} - \Delta L^\text{treatment}) \times 100 / \Delta L^\text{control} \]

Where: \( \Delta \) in Eqs. (4) and (5) describes the change in L or A 420 between time t (24 h) and the initial time t0 at room temperatures. Total colour change (\( \Delta E \)) was also used to evaluate browning potential according to the following equation:

\[ \Delta E = [(L_2 - L_1)^2 + (a_2 - a_1)^2 + (b_2 - b_1)^2]^{1/2} \]

EFFECT OF EXTRACTION METHOD OF SOME NATURAL EXTRACTS ON ENZYMATIC BROWNING OF APPLE JUICE

Hesham A. Eissa, Bahaa M. Mostafa, Gamil F. Bareh and A. A. Shouk

STATISTICAL ANALYSIS
Statistical analysis was performed using SPSS statistical package (Version 9.05) according to (Rattanathanalerk et al., 2005), analysis of variance (ANOVA) and least significant difference (LSD) was chosen to determine any significant difference among various treatments. P < 0.05 was selected as the level for significant differences.

RESULTS & DISCUSSIONS
EFFECT OF NATURAL EXTRACTS AND ITS EXTRACTION METHODS ON POLYPHENOLOXIDASE (PPO) ENZYME ACTIVITY OF APPLE JUICES

Red Delicious apple has one of the highest rates of enzymatic browning among several apple cultivars. The obtained results represent the enzymatic browning as polyphenoxidase (PPO) enzyme activity of the untreated and treated apple juices with different extraction methods (Figs 1-3). The results showed that the polyphenoxidase (PPO) enzyme activity of the untreated fresh apple juices increased sharply as compared to other treatments (Figs 1-3). These results are consistent with those reported by Dong et al., (1995) who found that the PPO-activity in fresh apple juices increased sharply compared to treated juices. The vegetables (cucumber, squash and pepper) and mushroom extracts did not show high browning result in high inhibition of enzymatic browning (PPO) in apple juice in all extraction methods.

Effects of water, alcoholic and ultra-filtration extracts on the apple juices PPO activities are shown in Figs 1, 2 and 3, respectively. Under the experimental conditions described above, the control samples without added extracts showed an increase in PPO activities up to 0.00065 (unit / gram) in apple juices. Watery extract of some vegetables and mushroom inhibited PPO enzyme activity but it was lower than natural ultra-filtration and alcoholic extracts in apple juice, as seen in Figs 1-3. The natural watery mushroom extract had higher inhibition effect of PPO activity than natural watery vegetables extract in apple juice because the watery extract of some vegetables was more viscous than mushroom extract, as shown in Fig 1. Ultra-filtration extract of cucumber had higher inhibition effect of PPO activity than natural ultra-filtration pepper and mushroom extracts in apple juice (Fig 2). Finally for alcoholic extract, of some vegetables and mushroom inhibited PPO enzyme activity but it had higher inhibition effect than natural ultra-filtration and watery extracts in apple juices (Figs 1-3). The natural alcoholic cucumber extract had higher inhibition effect of PPO activity than natural alcoholic pepper and mushroom extracts in apple juice (Fig 3). No PPO-activity was observed in apple juices treated with squash methanol extracts, as seen in Figs 3.

The decrease in PPO activity with different extraction methods probably resulted from the formation of oxidation reaction products derived from the natural compounds (such as ascorbic acid, sulfites, sulfur containing amino acids, organic acids and phenolic acids) in vegetables and mushroom extracts which inhibit PPO activity and possibly the pH degradation after processing at 25°C. However, the combination of different compounds may prevent enzymatic browning (PPO) better than a specific compound alone (Mi et al., 2002, Eissa and Salama 2002 and Iyidogan and Bayindirili 2004). These results are in agreement with those reported by Patricia et al. (1993). Eissa and Salama (2002) indicated that the treatments with cabbage, celery and fenugreek leaves water extracts inhibited the polyphenoloxidase activity in apple juices. Also, Wang & Lee (1996) reported that browning inhibitors in natural extracts of legumes that inhibited polyphenoloxidase had anti-browning activity in apple juice. However, a mean ascorbic acid content of raw vegetables (cucumber, squash and pepper) and mushroom extracts is about 36-40 mg/100 g (Franco-Vargas et al., 1995). The results of Gandia-Herrero, (2003) supported the assumption that the enzyme PPO is present in the cucumber skin, but its activity is inhibited. On the basis of the obtained results, the inhibitory action of some squash, pepper and cucumber compounds against PPO activity may be an indication of the benefits of the use of squash, pepper and cucumber in food to prevent browning. These results clearly showed that the squash and ‘Oyster’ alcoholic extract had the potential to inhibit apple PPO activity. Inhibitory effects were found regarding the browning of apple juice.

The inhibition of browning in apple has been reported by several researchers (Friedman and Molnar-Perl, 1990). Discoloration correlated well with the PPO activity and the concentration of phenolics (Fraignier et al., 1995; Murata et al., 1995). Consequently, brown pigmentation has been attributed directly to the catalysed action of PPO (Underhill and Critchley, 1993). The alternative treatments in order to control enzymatic browning due to PPO are usually accomplished by the addition of ascorbic acid, citric acid, benzoic acid, calcium chloride, cinnamic acid, cysteine, glutathione, and various combinations of these compounds.

inhibitory effect (%) of the natural vegetables and Oyster mushroom extracts by different extraction methods (water, UF and alcoholic) based on $A_{420\text{nm}}$ measurements (Eq.4) and L-measurements (Eq. 5) were calculated and cited in Tables 1-3. The total colour changes (ΔE) for all tested samples were calculated (Eq.6) from the hunter colour lab values and given also in the same tables 1-3. It is obvious that for all extracts there were some differences between percentage of inhibition based on measurement of $A_{420\text{nm}}$ and L-values. Under all tested conditions, squash showed higher inhibition values based on L-values than $A_{420\text{nm}}$ measurements compared with other extracts.

ΔE is the unit for computing the total color differences from the initial value. We found a good linear relation between Δ E and the the extracts treated apple juices with different extraction methods, as seen in Tables 1-3. Similar relation between Δ E and % inhibition of Δ $A_{420}$ and Δ L* in apple juices after storage for 24 hours at room temperature (25°C) revealed by the obtained results.

For all extracts treated samples the decrease in a*-values of the apple juices revealed an increase in the inhibition percentage than untreated samples. Such trend is in agreement with those of Son et al., (2001) and Ozoglu and Bayindirh (2002). The inhibitory effect of various natural vegetables and Oyster mushroom extracts with different extraction methods (water, UF and alcoholic) based on % Δ $A_{420}\text{nm}$ and % Δ L-measurements as well as Δ E are shown in tables 1-3 for apple juices, stored at 25 °C in the following decrease order squash > mushroom >cucumber > pepper > control in the case of treated apple juices. Also, The inhibitory effect of various extraction methods (water, UF and alcoholic) for natural some vegetables and Oyster mushroom extracts based on % Δ $A_{420}\text{nm}$ and % Δ L-measurements as well as Δ E are shown in tables 1-3 for apple juices, stored at 25 °C in the following decrease order UF > alcoholic >water in the case of treated apple juice compared to control samples. The results are in accordance with those of Meza et al. [1995], Eissa and Salama (2002), Mi et al., (2002) and Eissa et al (2006). The treatments especially squash and pepper extracts can prevent browning and colour changes in apple juices because they contain the sulphydryl groups, phenolic compounds, organic acids and ascorbic acid (Roshita et al., 2004; Iyidogan and Bayindirili 2004).

The aforementioned order showed noticeable variations at UF, watery and alcoholic extracts. It is of great importance to refer to the opinion of Cowan 1999 who investigated the use of natural extracts by different methods, a powerful anti-browning agent, is discussed more because of the potential hazards of chemical agents and their influence on PPO activity. No uniform correlation was found between the natural extracts and inhibition activity. Who attributed these findings to the possibility that, the natural extracts may undergo significant side reaction in preventing browning of fruits and vegetables.

As shown in Figures 1-6, all tested anti-browning natural of some vegetables and Oyster mushroom extracts exhibited higher inhibition activity compared with untreated samples. Extracts have been used as anti-browning agents for processing fruits and vegetables. They prevent enzymatic browning by reducing the quinone products to their original polyphenol compounds (Son et al., 2001).

Under tested storage conditions, the squash extract exhibited higher effect than other extracts regarding inhibitory effect on the basis of L- values- measurements (Table 1-3), whereas the highest inhibitory effect of squash by alcoholic extraction being of higher effective by 100 % than other extraction methods (water and UF). Such aforementioned level decreased to 90 % by UF for the same sample. These results are in accordance with those of Son et al., 2001, who evaluated the effect of various anti-browning agents on apple juices. The obtained results revealed that extracting by alcoholic and UF could be effective regarding anti-browning agents under investigated conditions. However, any natural extracts contains L-cysteine and sulfur-containing amino acid considered to be effective inhibitors of PPO (Buta et al., 1999; Gacche et al., 2004). These compounds prevent enzymatic browning by reacting with o-quinone to produce stable, colourless adducts instead of the brown pigments (McEvily et al., 1992). These results confirm those reported by Ozoglu and Bayindirh, (2002) who compared the effectiveness of a series of compounds for inhibition of browning in the apple juice.

Recently, Eissa and Salama (2002) showed that a natural extract of some leafy vegetables was efficient in preventing browning of dried apple rings. Also, Mi et al., (2002) suggested that juice and sliced apple could be protected from browning using ‘Enokitake’ mushroom extracts. The obtained results revealed that vegetables and ‘Oyster’ mushroom extracts were effective regarding inhibition of PPO activity, that it might be because they contain certain compounds (such as ascorbic acid, organic acids, phenolic compounds, L-cysteine and bisulphates) which are effective in inhibition of PPO-activity in apple juice. However, Ascorbic acid has received particular attention because of its multiple effects: it chelates copper, reduces α-quinones and acts as a competitive inhibitor of PPO (Pizzocaro et al., 1993). Also, L-Cysteine and sulphite compounds in all extracts prevent brown pigment formation by reacting with the quinine intermediates to form stable colourless compounds (Vamos-Vigyazo, 1995). The extracts also prevented the development of browning occurring in the apple juice. Moreover, the present study clearly showed that treatment of apple juice using some vegetables and ‘Oyster’ mushroom extracts prevented the browning. The adverse health effects of sulphites as well as increased regulatory scrutiny (McEvily et al., 1992) have created needs for alternatives chemical agents (George et al., 1999). The result showed that the ultra-filtration and alcoholic extract effectively inhibited the browning of apple juices, so it demonstrated that (1) vegetables and ‘Oyster’ mushroom extracts contain certain potential inhibitors of PPO; (2) these inhibitors are stable under room temperature (25 °C) for a certain time (24 hours); and (3) there are potentials of commercial application. A number of other antibrowning treatments, including reducing agents, acidulants, chelating agents, polyphenoloxidase inhibitors, inorganic salts and enzymes have been investigated but are not applied in commercial use (Sapers et al., 1989). Utilization of the the vegetables and ‘Oyster’ mushroom extract will be promised as a natural food additive for the prevention of color browning caused by PPO. Although effective compounds in some vegetables and ‘Oyster’ mushroom extracts in terms of a PPO inhibitor have not been identified, it's potential as an inhibitor of apple PPO. Further research will be required for the identification of effective compounds in natural extracts.

CONCLUSION

There are numerous of natural compounds capable to reduce the enzymatic browning; therefore the use of natural extracts is still stimulated to meet the demands for production of healthy food products having high quality. However, a natural extracts (squash, pepper, cucumber and Oyster mushroom) could also be used for substitution for chemical agents to delay browning of minimally processed

apple juices by inhibition the PPO-catalyzed browning. Besides being able to retain the colour and enzyme activity of the samples almost as good as the natural extracts treatment, is cheaper and is normally considered as a common item in the most of the households. Also, tested extracts were found to be good anti-browning agents in maintaining the storage quality of apple juice at room temperature. On the other hand, the different methods of extraction showed comparable results with squash, cucumber, pepper and Oyster mushroom extracts, so the use of these natural extracts is more economical.
